1 Introduction

1.1 Purpose of the Restoration Plan

This restoration plan has been developed by National Parks and Wildlife Service (NPWS) of the Department of Housing, Local Government and Heritage to set out proposals for restoration of raised bog and associated habitats at Raheenmore Bog Special Area of Conservation (SAC) (000582). This plan identifies technically feasible restoration measures for the various zones of the bog including the high bog, cutover bog and surrounding margins and provides details of progress on implementation of the restoration plan.

The restoration measures set out will enable nature conservation targets for Active Raised Bog (ARB) at this SAC to be met. Although the focus of the restoration plan is on ARB habitat, it is anticipated that restoration measures will also benefit other peatland habitats and can contribute to socio-economic benefits for the local community, improvements to biodiversity and reduced carbon emissions. Monitoring of this restoration plan will be undertaken to ensure that the intended restoration measures are successfully contributing to the achievement of the site-specific targets for ARB at Raheenmore Bog SAC.

Raheenmore Bog SAC is one of 12 project sites where comprehensive restoration was funded under the EU LIFE 2014-2020 programme to restore active raised bog in Ireland's raised bog SAC network.

Action 1.1: Develop restoration plan further in partnership with stakeholders.

This restoration plan will be developed further in conjunction with stakeholders to ensure that restoration is carried out in such a way that the conservation requirements of the site can be met, whilst minimising any impacts on adjacent land and maximising benefits to the local community. The plan will develop and change over time through input from stakeholders and **will be considered a living document**. The primary aim of this restoration plan is to ensure site-specific conservation objectives for Raheenmore Bog SAC can be met.

Section 2 of the restoration plan sets out the restoration measures that have been proposed for Raheenmore Bog. Section 3 outlines how a drainage management plan for Raheenmore Bog has been developed to support the implementation of this restoration plan. Section 4 describes potential for community benefits to be explored through the plan and Section 5 outlines progress with implementation of the plan at Raheenmore Bog.

Map 1 outlines the location and extent of Raheenmore Bog SAC. Map 2 illustrates the restoration measures that have been implemented to date as well as any proposed/outstanding restoration measures to be implemented at Raheenmore Bog.

This document provides an outline of the plan but is supported by detailed datasets that are available on the NPWS Restoration Maps Viewer. This map viewer provides NPWS with an up-to-date view of all restoration plan details and supporting information including status of landowner investigations, landowner consent, progress with construction and details of proposed and remaining restoration measures.

1.2 Raheenmore Bog SAC

Raheenmore Bog (SAC) is situated approximately 5 km north west of Daingean. The SAC includes the raised bog which developed in a small basin in the catchment of two major river systems; the Brosna to the west and the Boyne to the east. The peat is very deep, being up to 15m in places. The underlying rock is Carboniferous limestone, with overlying gravely glacial till and lacustrine deposits above this. Raheenmore Bog contains a large area of ARB in the central part of the bog which has a well-developed hummock hollow topography. The active raised bog comprises mostly sub-central

ecotope, with a small single area of central ecotope (Fernandez et al. 2014a).

The SAC has been selected for three Annex I habitats. These are:

- [7110] Active raised bogs
- [7120] Degraded raised bogs still capable of natural regeneration
- [7150] Depressions on peat substrates of the *Rhynchosporion*

*Priority habitats

The high bog is surrounded by a narrow margin of cutover bog that is no longer being cut. Some sections of old cutover have developed narrow strips of birch woodland. Much of the rest of the cutover comprises un-improved pasture and wet grassland. Mineral springs feeding the lagg zone have been reported from the western part of the site. Peripheral drains (up to 4m deep in places) almost completely surround the bog. This drainage has been shown to have had a serious effect on the bog (Kelly 1993). A network of old drains also occurs throughout the eastern part of the high bog.

The National Parks and Wildlife Service (NPWS) own much of the site and an extensive programme of drain blocking and other restoration works have been undertaken, including the construction of large bunds at the margins of the high bog. Raheenmore Bog is a classic example of a midland raised bog and the deepest remaining in Ireland. There has been considerable research and restoration work carried out on the site since the early 1990s.

This restoration plan has been developed to address restoration measures for these peatland habitats. Restoration at Raheenmore has been substantially completed through the EU LIFE funded Living Bog Project.

1.3 Site-specific conservation objectives

Detailed site-specific conservation objectives (SSCOs) aim to define the conditions necessary to maintaining or achieving the favourable conservation condition of a habitat or species at site level. The maintenance of habitats and species within sites at favourable condition will contribute to the maintenance of favourable conservation status of those habitats and species at a national level.

A conservation objective has been set for Raheenmore Bog SAC for ARB habitat using attributes and targets based on parameters set out in the Habitats Directive. In summary, one of the key targets is to restore the area of ARB to 70 ha. The area of ARB was reported as 52.3 ha during the 2011 monitoring survey and it has been determined that there is potential for 16.4 ha of Degraded Raised Bog (DRB) to be restored to ARB on the high bog following restoration measures. There is also long-term potential for 1.3 ha of bog peat-forming habitats (BPFH) to develop if restoration measures are undertaken on cutover areas. Several targets have been set for other attributes relating to the quality and condition of ARB habitat, including a target to restore adequate transitional areas to support/protect the active raised bog and the ecosystem services it provides. The restoration measures proposed by this restoration plan aim to achieve these targets. Further information on the SSCO's can be found in the Raheenmore Bog SAC conservation objectives document (NPWS, 2015a) and the conservation objectives supporting document – raised bog habitats (NPWS, 2015b).

2 Restoration measures at Raheenmore Bog SAC

2.1 Introduction

Hydrological processes are key drivers of raised bog ecology, as raised bogs are predominately fed by precipitation. For ARB to develop or be maintained, mean water levels need to be near or at the bog's surface for most of the year. Seasonal fluctuations should not exceed 20cm below ground

surface, and water levels in the peat should be within 10cm of the surface, except for very short periods of time (Kelly & Schouten 2002). Gentle slopes that limit intermittent lateral losses of water (through surface run-off) and encourage sustained water-logging are the most favourable to achieve these conditions. These conditions may be maintained on steeper slopes in areas of focused flow (flushes) (Mackin et al., 2017a; Regan et al., 2020). However, it will not be possible to raise the water level to high enough levels across the entire high bog surface, particularly approaching marginal areas, to enable ARB to develop. Even in high bog areas that do not have potential for ARB to form, water levels should be raised as necessary to support habitat for the areas where ARB can occur.

The main aim of restoration on raised bogs is to maintain or improve the quality of existing areas of ARB or improve the hydrological conditions that will allow ARB to develop in areas with suitable topographic conditions (gentle slopes and/or areas of focused flow). This requires measures to be implemented on both the high bog and cutover areas. Measures implemented on selected areas of cutover will also help to minimise the impact that drainage and cutting has had on the hydrological integrity of the high bog and support a diversity of other transitional wetland habitats (e.g. wet woodland and fen), as well as the species they sustain. Once restored, these transitional cutover zones may provide further ecosystem services through flood attenuation and water supply maintenance and purification, increased carbon sequestration and improvements to the site's overall biodiversity value.

The main restoration measures that may be considered for improving hydrological conditions on raised bogs include:

- Drain blocking (includes drains on both high bog and the margins)
- Removal of forestry/tree clearance
- Installation of marginal dams
- High bog excavation/re-profiling
- Inoculation with *Sphagnum* species
- Bunding on high bog or cutover bog.

Further details on each of these measures can be found in the Irish Wildlife Manual No. 99 'Best practice in raised bog restoration in Ireland' (Mackin et al, 2017b). Additional measures may be considered in particular instances where there are specific problems that are causing damage to an SAC. The most relevant restoration measures for Raheenmore Bog SAC are outlined in Section 2.2 – 2.6 below.

2.2 Blocking of high bog drains

Blocking high bog drains slows the flow of water off the surface of the bog and increases the water table in the peat. Drain blocking is a proven and effective restoration measure on Irish raised bogs with minimal maintenance requirements. The approach has been demonstrated at a number of raised bogs in Ireland with very positive results evident in less than 10 years (**Figure 2.1**) as outlined by Fernandez *et al.* (2014a).

Sometimes, there are concerns from local communities living close to raised bogs that drain blocking on the high bog will result in, or exacerbate, flooding. Blocking high bog drains, in fact, slows the flow of water off the bog potentially reducing the frequency and magnitude of flood events by restoring the hydrological function of the bog. To address these concerns NPWS developed a drainage management plan for Raheenmore Bog in advance of the implementation of the restoration plan, with further details of this plan outlined within section 3.

Figure 2.1 Example of a peat dam to block a typical high bog drain

Action 2.1: Continue to monitor within high bog drains at Raheenmore Bog SAC.

All high bog drains have been blocked on Raheenmore Bog including a denser network of drains on the eastern side of the high bog. However, ongoing monitoring of the drain blocking activity is required to ensure dams do not fail over time. Details of the locations of blocked drains on the high bog can be found in Map 2.

2.3 Blocking of drains on cutover bog

Blocking of cutover drains slows the flow of water off the cutover areas and increases the water table in the surrounding peat. This can help to reduce the rate of infiltration through the high bog and can lead to conditions that allow peat to form on the cutover (**Figure 2.2**).

Drain blocking on cutover areas has been carried out at a number of raised bogs in Ireland to date resulting in the development of peat-forming vegetation on cutover areas. As with blocking of high bog drains, there are sometimes concerns from local communities living close to raised bogs that drain blocking on cutover bog will result in, or exacerbate, flooding. Blocking drains on cutover bog can slow the rate at which water is lost from the bog therefore potentially reducing the frequency and magnitude of downstream flood events. This restoration measure is primarily focused on former spread-grounds and only in very rare occasions, where it is absolutely essential, includes agricultural land. Drains in these areas will only be blocked in agreement with landowners and where there is a suitable hydrological barrier such as a functional drain to prevent impacts outside of the restoration area.

Figure 2.2 Water table at the surface of cutover bog following successful drain blocking resulting in *Sphagnum* development less than 10 years after drain blocking (this was previously an area of bare peat)

Action 2.2: Block drains on selected cutover areas within Raheenmore Bog SAC.

Almost all of the cutover drains have already been blocked on Raheenmore Bog, with only a small number of drains remaining to be blocked. However, ongoing monitoring of the drain blocking activity is required to ensure dams do not fail over time. Blocking of cutover drains may reduce ongoing subsidence of the high bog. In some areas this will also lead to the development of peat forming habitats. It is proposed that these drains are blocked, primarily with peat dams, with some plastic reinforcements where necessary to prevent erosion. The required conditions are for the water table to be maintained at or close to the surface, therefore large areas of standing water or deep pools are not desired. Details of the locations on the cutover where it is proposed to block drains can be found in Map 2.

2.4 Contour bunding

Contour bunds on the high bog aims to reduce the rate of lateral flow through the upper layers of the peat. In contrast to some other bunding techniques, contour bunding is not intended as a means of impounding surface water. This method involves excavating a trench 1.5-2.0m deep, re-

compacting peat into the trench and building a slightly raised bund 25-30cm above the current ground surface. In addition, these bunds have 5m long 'finger bunds' constructed using the same technique at approximately 25m spacing to prevent flow along the bund which may lead to erosion. After 1-2 years it is anticipated that the bund will have subsided close to current ground level and therefore will not appear as a prominent feature on the bog surface.

Figure 2.3 Example of a contour bund constructed at Knockacoller Bog SAC, Co Laois

Contour bunds are most effective where there is cracking or slumping in the upper layers of the peat as the re-compacted trench assists in sealing up these cracks and slows the flow rate through the peat, supporting a higher water table behind the bund. The key issue with this technique is that the extent of the impact extending back into the bog depends on the hydraulic gradient (which is closely correlated to surface slope). As a result, the extent of impact from such bunds is likely to be extremely limited where the surface slope at the margins is steep. This method is best suited to sites with a relatively gentle slope towards the margins or as a means of effectively blocking a dense network of shallow surface drains on the high bog. Ground conditions will play an important factor in whether the bund can be constructed in such circumstances, therefore this method is most effective on drier sites where machines can operate safely and effectively.

Action 2.4: Assess the feasibility of constructing contour bunds at Raheenmore Bog SAC

There may be potential for contour bunding on some areas of the cutover at Raheenmore Bog. This measure was not used on Raheenmore during the Living Bog Project, but ongoing reviews of the restoration plan should determine whether this measure is applicable. The surface slopes are relatively gentle on Raheenmore and there may be some cracking associated with the deep drainage to the east of the bog, therefore, contour bunding may be a suitable restoration option to consider. Further opportunities for implementation of this measure should consider the response of the vegetation to existing restoration measures.

2.5 Cell bunding

Cell bunding involves the creation of individual cells, consisting of a cutoff walls extending into the peat substrate and protruding above the ground surface to create a water table close to or slightly above the ground surface (maximum depth typically 10-20cm). The approach permits the interception of laterally flowing groundwater by low permeability cutoff walls, while the surface bunds prevent lateral discharge of surface water; this also encourages recharge to the underlying water table, helping contribute to the water balance, while also maintaining an elevated water table in those areas up gradient of standing water. Due to topographic variability the depth of water will also vary resulting in enhanced ecological diversity across the banded area.

Cell bunds are typically constructed by excavating a trench 1.0-1.5m deep, recompacting the excavated peat into the trench and constructing a bund 0.5-0.6m high above the ground surface (Figure 2.3). Water level control structures (pipes or overflow weirs) are incorporated into these cells as a means to regulate water levels and evenly distribute water across the site.

Figure 2.4 Example of existing cell bund constructed at Cloncrow Bog NHA (the vegetation in this photo has developed in the 2 years since cell construction)

Action 2.5: Assess feasibility of constructing cell bunding at Raheenmore Bog SAC

There may be potential for cell bunding on some additional areas of the cutover at Raheenmore Bog. Opportunities for implementation of this measure should consider the response of the vegetation to existing restoration measures.

2.6 General site management

In addition to the proposed measures, it is important that the restoration plan contributes to improving general site management. This includes considering issues such as:

- Fire prevention and response
- Management of littering/fly-tipping

Burning of the high bog can result in significant damage to a raised bog by removing peat-forming vegetation which reduces the capacity of the peat to retain water. This causes much more rapid surface run-off and therefore can result in more widespread drying out and increased peak flows in surrounding streams. No recent fires have been reported at Raheenmore Bog but the bog has been affected by burning in the past.

Issues such as littering and fly-tipping are also common problems on raised bogs. Depending on the nature of the material dumped this can lead to pollution in surrounding areas.

Action 2.6: Prepare a fire prevention and control plan for Raheenmore Bog SAC in consultation with local stakeholders.

It is proposed that a fire prevention plan is developed for Raheenmore Bog SAC to identify past occurrences of fires, the likely causes and develop an effective plan to prevent fires in future as well as an appropriate response should a fire occur in the future. Issues such as fire prevention and management of littering/fly-tipping also need to be addressed as part of a wider strategy of raising public awareness on the importance of these habitats.

3 Drainage Management Plan

One issue that can cause concerns, particularly for local stakeholders, relates to whether restoration may result in increased flooding in the surrounding area. In many instances bog restoration has the opposite effect by returning more natural hydrological conditions whereby flow is attenuated and reaches the surrounding watercourses more slowly than when drains were present. This is evident at bogs such as Killyconny Bog SAC (000006) where extensive restoration has been carried out on cutover bog and there have been no adverse impacts on adjoining agricultural land.

Nonetheless, many individuals may remain unconvinced on these issues until several years after restoration has taken place. Therefore, in order to provide reassurance, an integrated drainage management plan for the bog and its surroundings has been developed as part of this restoration plan. The drainage management plan will be intended to support the conservation objectives for Raheenmore Bog SAC by ensuring the drainage network can be maintained without impacting on the conservation objectives. The plan assesses instances existing impediments to the effective management of the drainage network (e.g., undersized culverts or channels) and provides recommendations in relation to remedial works and maintenance works going forward. Implementation of such measures will ensure that the risk of flooding will be significantly reduced.

Action 3.1: Engage with local stakeholders in relation to the implementation of recommendations of the Drainage Management Plan for Raheenmore Bog SAC.

Implementing the recommendations of this plan will require engagement with local stakeholders to ensure any management actions completed are carried out in line with best practice guidance.

4 Community benefits

Through consultation with the local community and other stakeholders it will be possible to develop ideas for maximising socio-economic benefits for the local community through restoration. These might include building or improving existing facilities, where appropriate (i.e., tracks, board walks,

bog bridges), encouraging the creation of small tourism enterprises, promoting the benefits to human health and well-being and enhancing the value of the site as an educational resource. There are many cases where local communities, including local businesses, are actively involved in or supporting the conservation and restoration of raised bogs across the country. Examples of this are found at Abbeyleix Bog (Co. Laois), Carrownagappul Bog SAC (Co. Galway), Girley Bog Natural Heritage Area (NHA) (Co. Meath), Lodge Bog (Co. Kildare) and Scohaboy Bog NHA (Co. Tipperary).

Raheenmore Bog already offers significant potential for recreation and amenity; there is already an area used as a carpark and there is potential to develop access tracks and walking routes. There is significant potential for investment in upgrading, expanding and maintaining these tracks as access routes for amenity and recreation. Any proposed amenity facilities will need to be implemented in a way that does not impact on the site-specific conservation objectives for the site.

Apart from immediate economic benefits, the restoration of raised bogs can provide many other benefits to the wider community, such as provision of clean water, flood attenuation and water flow regulation, preservation of archaeological artefacts and other sources of historical knowledge and, not least, helping Ireland reduce its national greenhouse gas emissions and, therefore, helping to combat climate change.

Action 4.1: Optimise the community benefits of the restoration plan.

As the restoration plan is further developed and implemented, opportunities to improve the recreation and amenity value of the bog and surrounding areas and promote local initiatives, while protecting and enhancing its natural values, will be explored by and with the local community. Promoting community involvement in the long-term management of the site both during and after restoration measures are carried out, will be encouraged.

5 Restoration Plan Implementation

5.1 Preparatory

Prior to implementation of the restoration plan several preparatory actions are required before construction of restoration measures can commence. A summary of these preparatory actions is outlined below:

- Hydrological characterisation – collation of existing hydrological data, hydrological surveys, instrumentation with monitoring data (where necessary);
- Review of proposed restoration measures in line with best practice at the time of implementation (including exploring opportunities to implement enhanced measures);
- Detailed ecological surveys (primarily comprising surveys of cutover areas, but where necessary also includes high bog areas e.g., if ecotopes have not been surveyed in many years);
- Landownership Investigations (investigations into ownership, turbary rights etc.);
- Stakeholder consultation and community engagement (meeting with stakeholders to outline restoration plans and consider any concerns raised by the local community);
- Compensation/land acquisition (compensation or acquisition of lands required to implement the required restoration measures on private lands);
- Appropriate Assessment Screening;
- Compilation of tender/construction documents including preparation of health and safety

file;

- Surveying and setting out of the works;
- Implementation of restoration measures (including construction supervision and contract administration);
- Post-works inspections and preparation of as-built survey information;

Update of restoration plan to outline works completed and remaining works required in future.

5.2 Progress to date

Significant progress has been made in implementing the proposed restoration plan at Raheenmore Bog SAC, both in terms of progress with preparatory actions as well as implementation of substantial restoration measures across the SAC. A summary of progress to date is outlined below:

5.2.1 Hydrological characterisation

Status – Complete

Detailed hydrological characterisation of Raheenmore Bog SAC has been completed. This comprised detailed surveys of the high bog and cutover carried out as part of the Living Bog Project to collect data to enable the restoration plan to be refined. This was supported by a significant amount of research completed on the bog since the early 1990s. A hydrological monitoring network was established in 2018, comprising piezometer nests at eight locations across the bog (high bog and cutover). These were monitored at frequent intervals to assess the hydrological impact of restoration measures and this information is used as a feedback mechanism in reviewing the restoration plan.

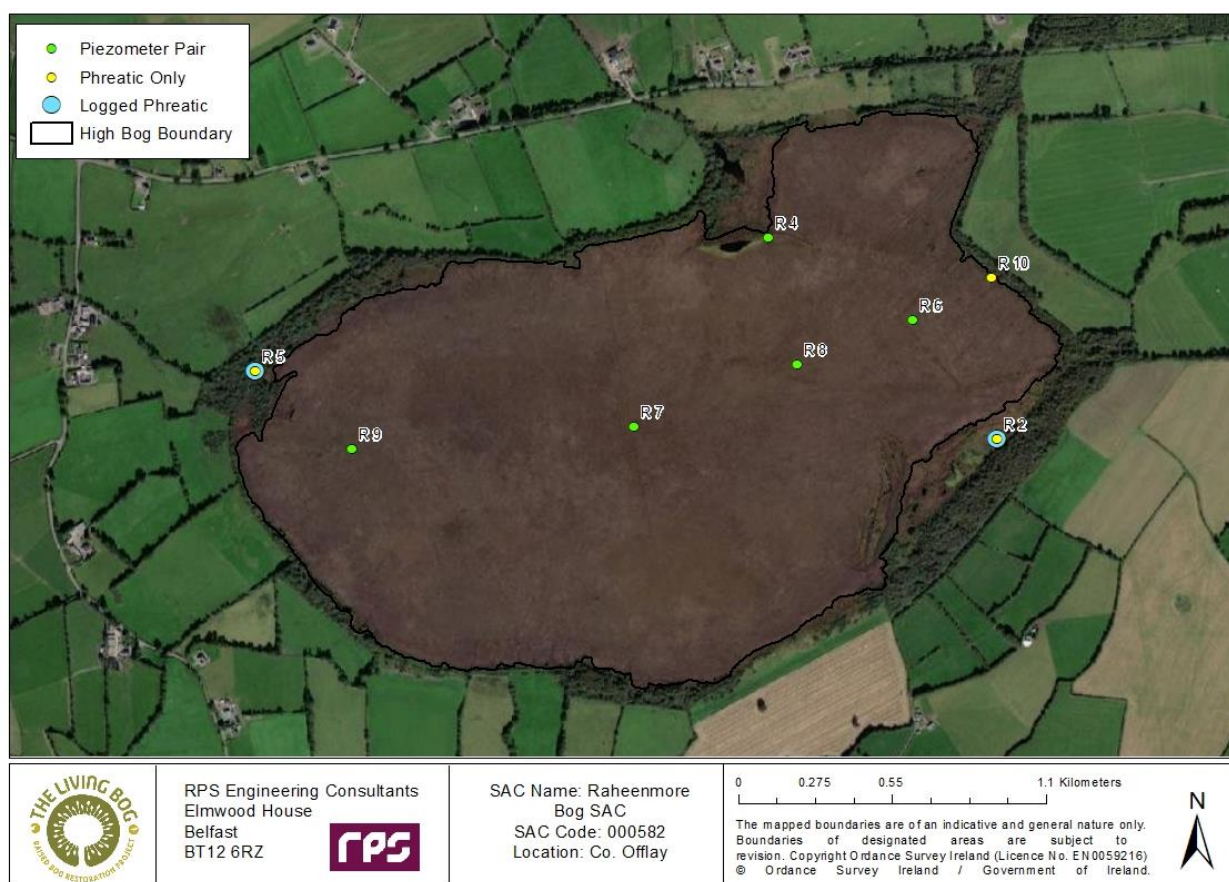

Figure 5.1 Location of hydrological monitoring network at Raheenmore Bog SAC

Figure 5.2 Example of hydrological monitoring at Raheenmore Bog SAC illustrating response to drain blocking on cutover with the water table rising from 30cm below ground surface to remaining within 20cm of ground surface at all times.

5.2.2 Review of restoration proposed measures in line with best practice at time of implementation

Status – Complete

Following detailed hydrological characterisation of Raheenmore Bog SAC in 2018, a comprehensive review of proposed restoration measures was completed. Details of the restoration measures at Raheenmore are illustrated in Map 2.

5.2.3 Detailed ecological surveys

Status - Complete

The most recent ecotope survey of Raheenmore Bog SAC was completed in 2016, prior to restoration measures being implemented. This survey determined that active raised bog (7110) covered 45.8ha of the high bog in 2016 (Crowley & Smith, 2022) which compares to 52.31ha of ARB mapped during the previous ecotope survey in 2013 (Fernandez et al. 2014). These surveys show that the active raised bog is decreasing prior to restoration measures being implemented. Five of the twelve Living Bog sites were surveyed in 2021 post restoration and all five sites shown an increase in active raised bog area. This would suggest that restoration measures are working across the bogs although until another survey is completed it cannot be sure. Future monitoring will be completed by NPWS when the vegetation has had more time to respond to restoration measures, with a full analysis of the increase in extent of ARB scheduled to be carried out by the NPWS raised bog monitoring programme 2022-24.

In addition to the high bog survey, a methodology for detailed vegetation mapping of cutover habitats was developed as part of the Living Bog Project and published as Irish Wildlife Manual No.

128 'The Habitats of Cutover Raised Bog' (Smith & Crowley, 2020). A cutover survey carried out in accordance with this methodology was completed at Raheenmore which identified that there are already 0.2ha of high *Sphagnum* areas throughout the cutover area, although the cutover was found to be dominated by Low *Sphagnum* types. No significant increase in the area of high *Sphagnum* vegetation types is expected following rewetting measures (Crowley & Smith, 2022). The high bog and cutover surveys completed as part of the Living Bog Project provides a baseline status that can be used to monitor the results of restoration measures in future.

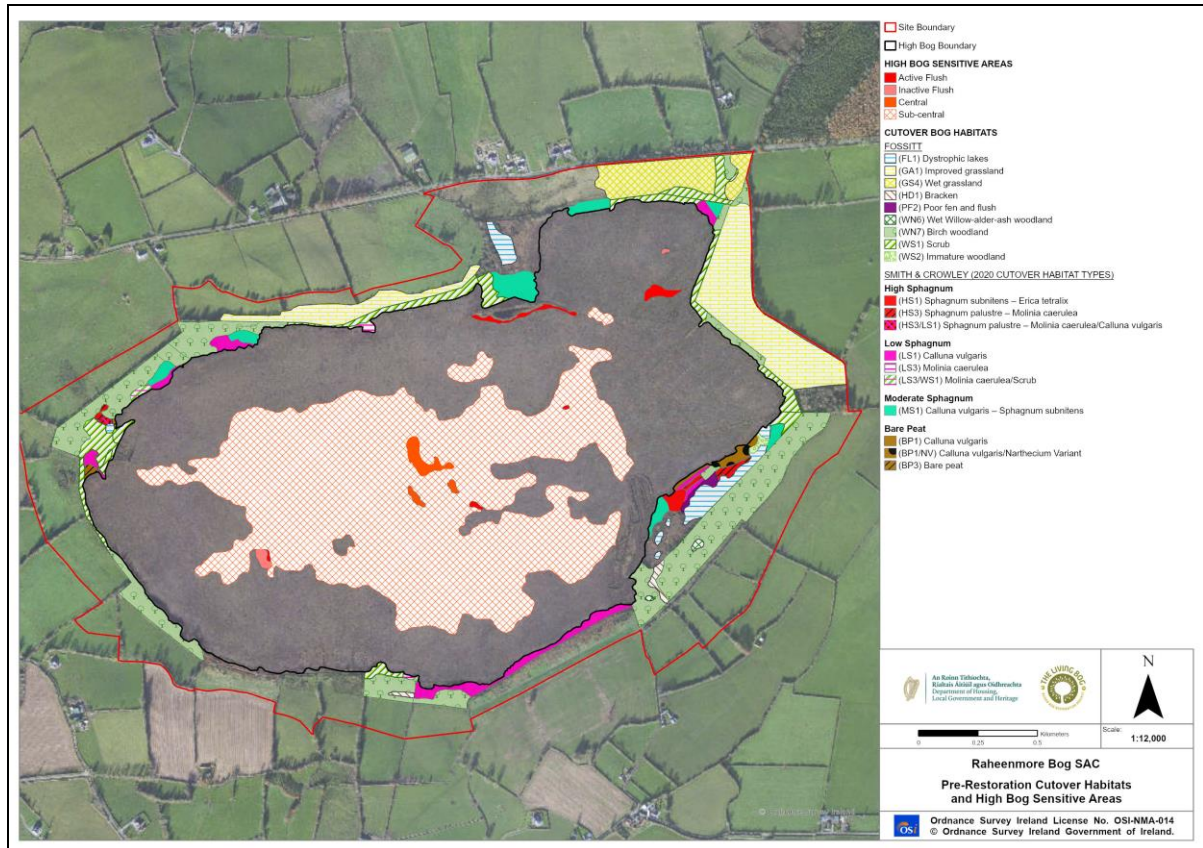

Figure 5.3 Ecological monitoring results (Pre-Restoration)at Raheenmore Bog SAC illustrating high bog and cutover vegetation types

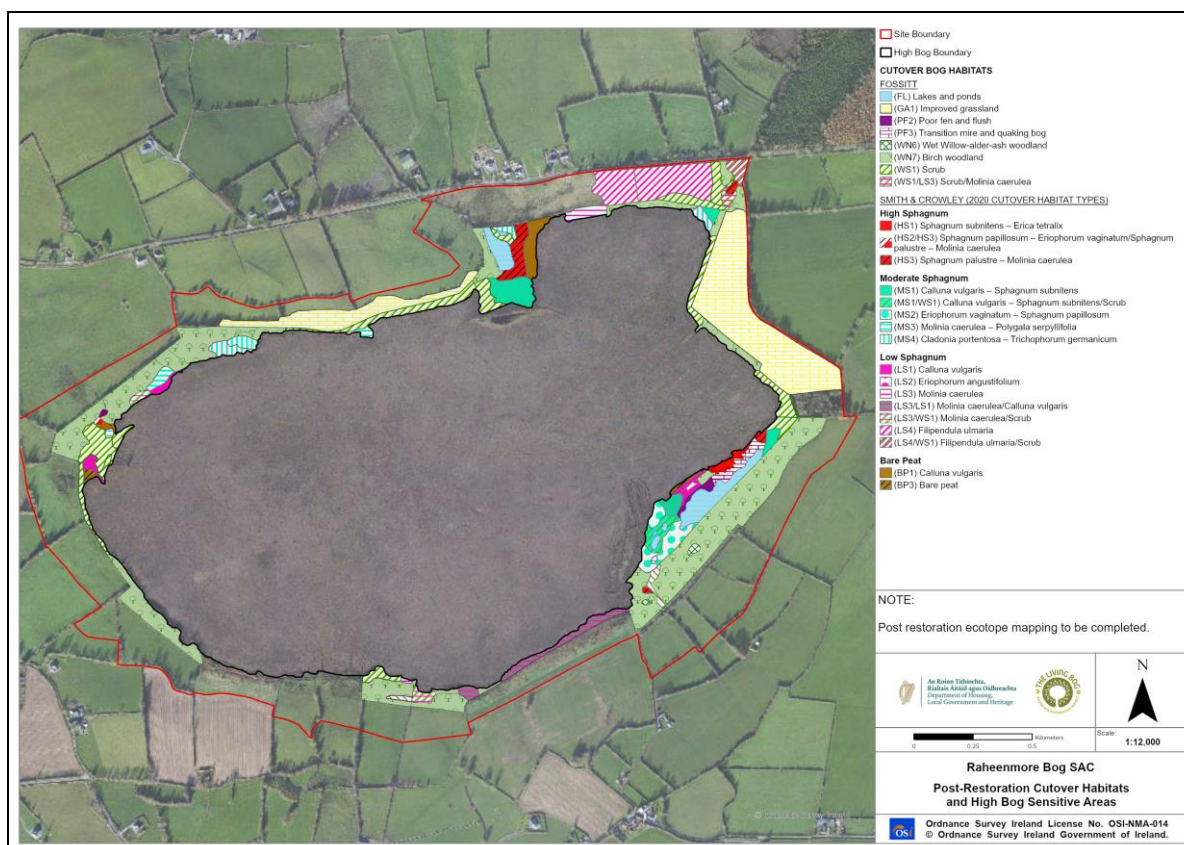

Figure 5.4 Ecological monitoring results (Post Restoration) at Raheenmore Bog SAC illustrating high bog and cutover vegetation types

5.2.4 Landownership Investigations

Status – Complete

Comprehensive landownership investigations were completed at Raheenmore Bog SAC as part of the Living Bog Project. The investigation identified that a significant portion of the bog is in public ownership with some private ownership across the bog, particularly around the margins. In addition, there are a large number of turbary right holders. This process allowed identification of key stakeholders to meet during the stakeholder consultation and community engagement phase.

5.2.5 Stakeholder consultation and community engagement

Status – Complete

Comprehensive stakeholder consultation and community engagement was carried out at Raheenmore Bog SAC as part of the Living Bog Project. The Living Bog Project team developed strong working relationships with key members of the local community. The team held meetings with turf cutters, landowners and interested community groups. At these meetings project aims, and restoration plans were presented to the stakeholders. This has included meeting with all private individuals owning the freehold or having a turbary right at the bog.

5.2.6 Compensation/land acquisition

Status – Complete

Compensation has been offered to and accepted by almost all qualifying landowners and turbary right holders within the bog which enabled the restoration works to proceed at the bog.

5.2.7 Appropriate Assessment Screening

Status – Complete

An Appropriate Assessment Screening report was prepared to consider the potential for significant effects on any European Sites from the implementation of the restoration plan at Raheenmore Bog SAC. As the bog has been selected as a Special Area of Conservation for the presence of raised bog habitats, the proposal to allow restoration measures to take place in Raheenmore Bog SAC **is directly connected with and necessary to the management of this site as a European site**. The proposed restoration measures are essential to support the reestablishment of appropriate hydrological conditions within the SAC to enable nature conservation targets for Active Raised Bog (ARB) at this SAC to be met.

However, following a precautionary approach and to inform a risk assessment, a screening for Appropriate Assessment report was prepared to assess, in view of best scientific knowledge and in view of the conservation objectives of those European sites considered, whether or not the project, individually or in combination with other plans or projects, is likely to have a significant effect on any European site.

The findings of this screening exercise determined that the proposed restoration measures:

- Will not give rise to potential likely significant effects on the Qualifying Interests/Special Conservation Interests of any other European site within the project's zone of influence, in view of best scientific knowledge and in view of the conservation objectives of those sites; and
- Will not give rise to potential in-combination or cumulative effects with the other plans or projects considered.

5.2.8 Compilation of tender/construction documents and Health & Safety file

Status – Complete

A work package comprising details of restoration measures that could be implemented was compiled by the Living Bog Project Team, which included detailed specifications for the proposed measures. In addition, a health and safety file was compiled to ensure the works could be carried out in accordance with the Safety, Health and Welfare at Work (Construction) Regulations. Generally, this work involves the following activities:

- Identify hazards arising from the design of the various schemes.
- Eliminate these hazards, or where not practicable to do so, reduce the risk of these hazards.

5.2.9 Surveying setting/out of the works

Status – Complete

The surveying and staking out of drains and dams can be difficult due to the nature of the bog environment. Vegetation and soft ground conditions can make identification of features and surveying of same difficult and potentially dangerous. The setting out of the works is generally done using bamboo stakes to mark the locations of the restoration measures that are to be constructed such as the dams or bunds. All works carried out as part of the Living Bog Project were set out as required which facilitated work being completed. This activity provides an additional opportunity to review the restoration measures in detail on the ground and where necessary minor modifications can be made (e.g., adjusting the placement of particular dams due to dense vegetation coverage or alignment of bunds due to ground conditions). This ensure that the risk of damage to the raised bog is minimized as inadequate planning can increase the risk of machines entering unsuitable areas.

5.2.10 Implementation of restoration measures

Status – Complete

All of the proposed measures as part of the Living Bog Project were completed as required at Raheenmore Bog SAC. This includes construction of 217 dams, which were all constructed from peat.

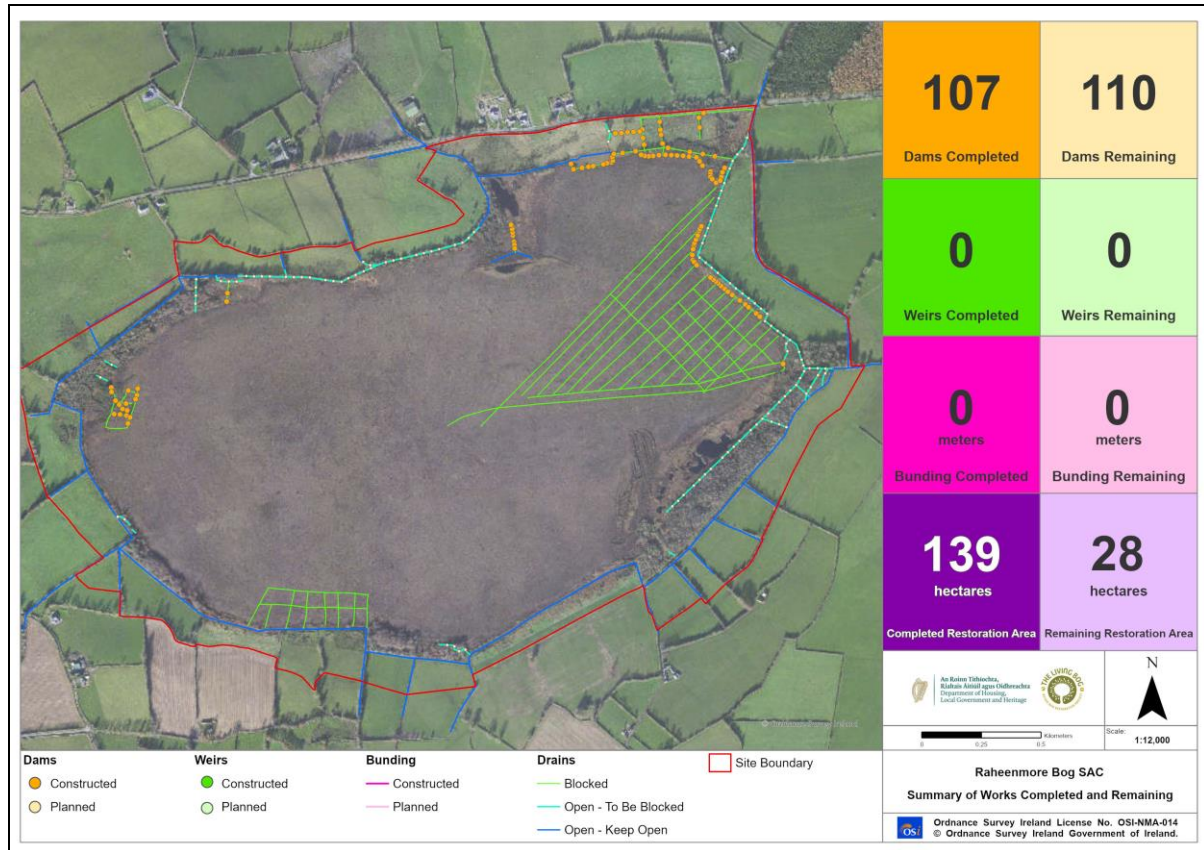

Figure 5.4 Summary of works completed to date

5.2.11 Post-works inspections and preparation of as built survey information.

Status – Phase 1 Complete (further phases required)

Post-works inspections have been completed and an as-built drawing was prepared by Bord na Móna on behalf of the Living Bog Project (summarised in Figure 5.4). This included detailed aerial surveys of the bog to collect high-resolution ortho-imagery and to ensure a detailed as-built drawing could be prepared.

Figure 5.7 Example of rewetting on the margins of Raheenmore Bog SAC from drain blocking in the 1990s

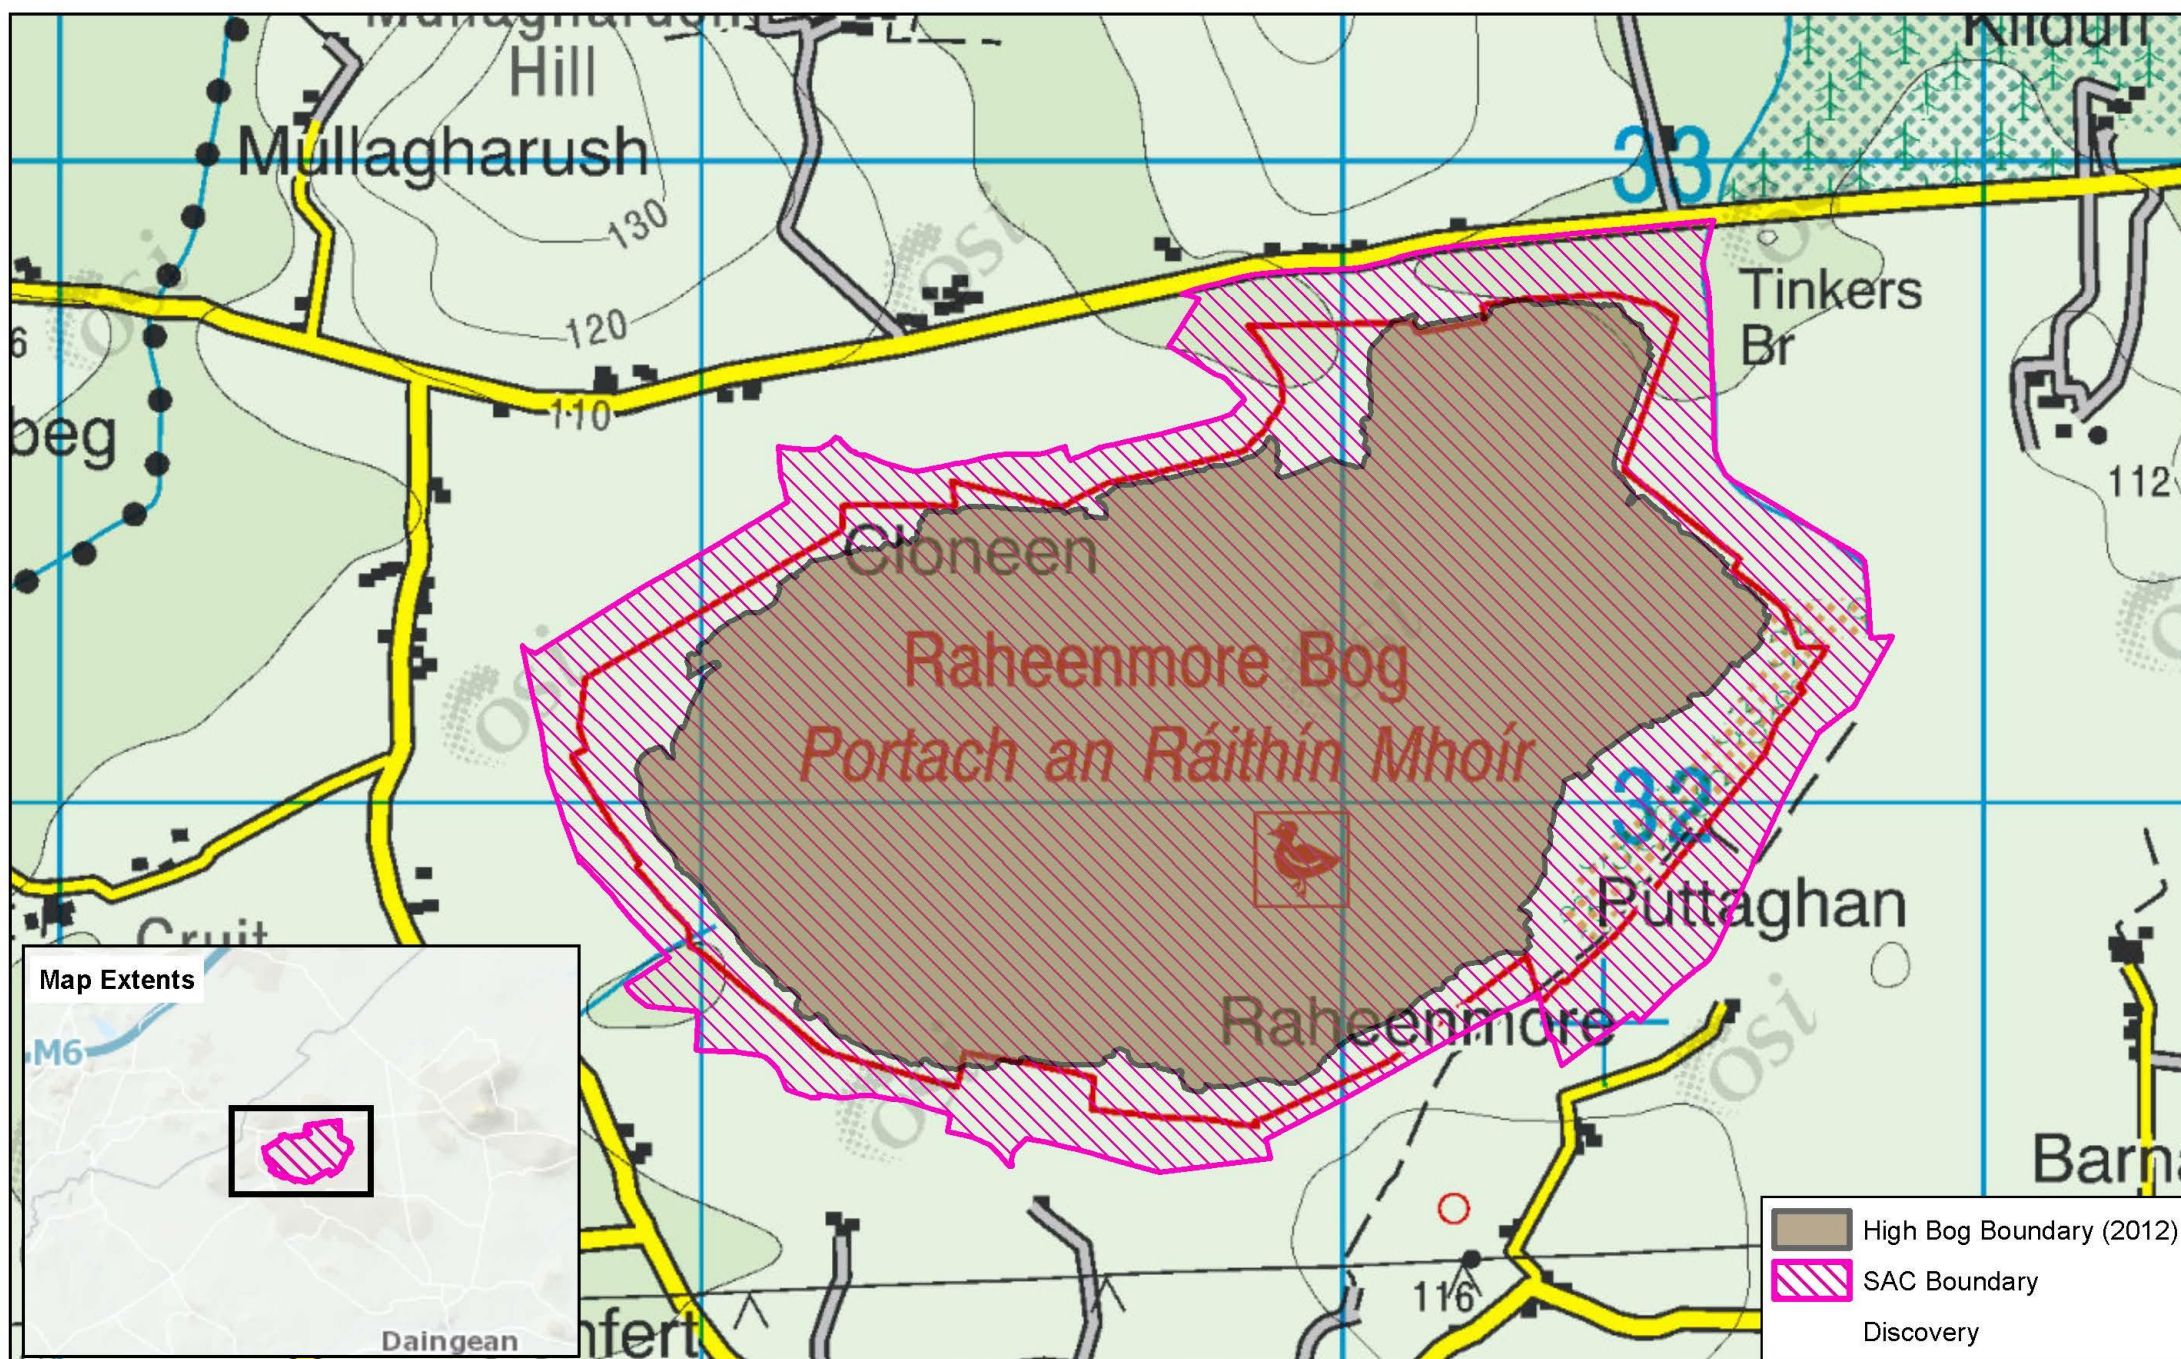

Figure 5.8 Example large marginal bund constructed at the edge of the high bog at Raheenmore Bog SAC in the 1990s

5.2.12 Update of restoration plan to outline works completed and remaining works required in future.

Status – ongoing

This restoration plan has been updated with the details of the works completed to date as part of the Living Bog and previous NPWS restoration projects. At present some restoration works are outstanding including the blocking of marginal drains. However, this is a complex issue that requires buy-in from stakeholders. In addition, as future monitoring surveys are completed by NPWS the need for additional restoration measures will be considered (such as the need for measures such as contour bunding) and this restoration plan will be updated as required. This restoration plan will also be reviewed on an ongoing basis as experience and best-practice evolves nationally and internationally.

7 Glossary & Acronyms

ACTIVE RAISED BOG (ARB)	Areas of uncut raised bog where the conditions are right for peat to continue to form, and where species of plants and animals typical to intact bogs can thrive. ARB is listed as a priority habitat in Annex I of the Habitats Directive.
ANNEX I	Annex I of the EU Habitats Directive lists natural habitats types of Community interest whose conservation requires the designation of SACs.
ANNEX II	Annex II of the EU Habitats Directive lists animal and plant species of Community interest whose conservation requires the designation of SACs.
BIODIVERSITY	A general term used to describe all aspects of biological diversity including the number of species present in a given environment, the genetic diversity present within a species and the number of different ecosystems present within a given environment.
BOG WOODLAND	Woodland formed on a wet peaty substrate, with permanently high groundwater level. The water is poor in nutrients (ombrotrophic) and the ground surface has high cover of bog moss species, with active peat accumulation taking place. Bog Woodland is listed as a priority habitat in Annex I of the Habitats Directive. It differs from dry woodland on bog where peat accumulation is not taking place.
BUNDING	An impervious embankment of material (peat or other) that provides a barrier to retain water behind it.
CARBON SEQUESTRATION	The capture and long-term storage of atmospheric carbon dioxide, including that accumulated by a bog or fen.
CATCHMENT	An area of land contributing water that drains to a defined point. The term river catchment refers to the area of land that drains into a particular river system and is synonymous with the term drainage basin or watershed.
CUTOVER	Areas of bog that have been previously cut (by hand or by mechanical means), although not down to the underlying inorganic substrate. Cutover areas normally consist of a mosaic of cut areas, face banks, pools, drainage ditches, uncut areas of peat, scrub, grassland etc.
DEGRADED RAISED BOG (DRB)	The area of high, uncut bog which has been damaged by human activities but which could be restored to active raised bog again through restoration measures within a period of 30 years. It is listed in Annex I of the Habitats Directive.
ECOLOGY	The study of the interactions between organisms, and their physical, chemical and biological environment.
ECOSYSTEM SERVICES	Humankind benefits from a multitude of resources and processes that are supplied by ecosystems. Collectively, these benefits are known as ecosystem services and include products like clean drinking water and processes such as the decomposition of wastes.
EROSION	The processes whereby the materials of the earth's crust are dissolved, or worn away and simultaneously moved from one place to another by natural processes which include weathering, solution, corrosion and transportation.

EVAPOTRANSPIRATION	Water loss to the atmosphere from soil and other surfaces (evaporation) and vegetation (transpiration).
FACEBANK	Areas at the edge of the high bog where peat cutting has taken place. This is an ecotope that is highly degraded and absent of typical <i>Sphagnum</i> species.
FAUNA	Animal life.
FAVOURABLE CONSERVATION CONDITION	This is the condition of a habitat or species considered to be favourable at site level. Favourable conservation condition is defined by site-specific conservation objectives (SSCOs). The maintenance of habitats and species within sites at favourable condition will contribute to the maintenance of favourable conservation status of those habitats and species at a national level.
FAVOURABLE CONSERVATION STATUS	According to the Habitats Directive the conservation status of a natural habitat will be taken as "favourable" when: its natural range and areas it covers within that range are stable or increasing, and the specific structure and functions which are necessary for its long term maintenance exist and are likely to continue to exist for the foreseeable future, and the conservation status of its typical species is favourable.
FLORA	Plant life.
FLOW ATTENUATION	Slowing flow of water out of an area. This is a common method for reducing risk of flood in urban areas whereby diversion channels store water in attenuation ponds. Intact peatlands typically offer natural flow attenuation through slowing flow as a result of higher storage capacity and increased hydraulic roughness, while degraded peatlands are much less effective at attenuating flow as the peat is dried out encouraging overland flow.
HABITAT	Refers to the environment defined by specific abiotic and biotic factors, in which a species lives at any stage of its biological cycle. In general terms it is a species' home.
HABITATS DIRECTIVE	Council Directive 92/43/EEC of 21 May 1992 on the conservation of natural habitats and of wild fauna and flora.
HEAD	Hydrological term which is a measure of the height to which water can raise itself above an arbitrary given level or datum.
HIGH BOG	The area of bog which has not previously been cut.
HYDROLOGICAL PROCESSES	The movement of water through a catchment area including freshwater and seawater inputs, water level changes and drainage mechanisms which are all influenced by the underlying geology.
LAGG	A term used to describe the natural habitat that occurs in the transitional zone between the bog and the mineral soil around a raised bog. Few intact lagg

	zones remain around raised bogs in Ireland as they are typically the first location to be damaged by drainage.
LIDAR	A remote sensing technology that measures vertical surface elevation by illuminating a target with a laser and analysing the reflected light usually obtained using a low-flying aeroplane. This provides detailed information on the surface elevations across an area.
LIFE	An EU financial instrument supporting environmental and nature conservation projects throughout the EU.
MARGINAL DRAIN	Drains on the margins of a raised bog typically on cutover for the purpose of draining spread-grounds to facilitate turf-cutting.
MICROTOPOGRAPHY	Variations in elevation at a relatively small scale. Generally the higher points are no more than a metre higher than the low points, and only a couple of metres across. On a high bog this consists of hummocks, hollows, pools, flats and lawns.
MINEROTROPHIC	Refers to soils and vegetation whose water supply comes mainly from streams or springs. This water has flowed over or through rocks or other minerals, often acquiring dissolved chemicals which raise the nutrient levels and reduce the acidity.
NATURAL HERITAGE AREA (NHA)	These are conservation areas designated for protection under The Wildlife (Amendment) Act 2000. NHAs are considered important for the habitats present or which holds species of plants and animals whose habitat needs protection.
NPWS	National Parks and Wildlife Service.
OMBROTROPHIC	Refers to a type of peatland that receives all of its water and nutrient from precipitation falling directly on its surface.
PIEZOMETER	A piezometer is a device used to measure head. In the case of groundwater a piezometer will provide head at a given point.
PEAT-FORMING HABITAT	These are habitats where peat is actively forming. It includes typical ombrotrophic raised bog vegetation as well as lagg or fen vegetation that indicate that peat is actively forming.
PRIORITY HABITAT	A subset of the habitats listed in Annex I of the EU Habitats Directive. These consist of habitats which are in danger of disappearance and whose natural range mainly falls within the territory of the European Union. These habitats are of the highest conservation status and require measures to ensure that their favourable conservation status is maintained.
RAISED BOG	Rain-fed peatland ecosystems that develop primarily in areas with topographic depressions, where drainage may be impeded by a high groundwater table, or by low permeability of the underlying substrata such as clay. Peat accumulation, over time, elevates the ground surface above surrounding areas to form a raised dome.
RESTORATION ZONE	A specified area within a site where restoration measures have been proposed. Restoration zones have been defined for each raised bog SAC based on factors including hydrological conditions, existing and expected habitats following restoration. This allows restoration measures for each raised bog SAC to be split into manageable units.
SITE-SPECIFIC	

CONSERVATION OBJECTIVE	A site-specific conservation objective aims to define the favourable conservation condition of a habitat or species at site level. The maintenance of habitats and species within sites at favourable condition will contribute to the maintenance of favourable conservation status of those habitats and species at a national level.
SPECIAL AREA OF CONSERVATION	Area designated for the conservation of habitats and/or species under the Habitats Directive.
SPREAD-GROUNDS	Area where turf is spread after cutting to dry out, typically drained cutover bog or agricultural areas adjacent to the high bog.
STATUTORY NATURE RESERVE	A Statutory Nature Reserve is an area of nature conservation interest that has been designated by Ministerial Order under the Wildlife Act, 1976.
SUBSIDENCE	Term referring to the sinking of land resulting from natural activity or human activity. Within peat subsidence occurs due to loss of water for example as a result of drainage.
TILL	Geological term referring to unsorted material deposited by glacial ice and showing no stratification. It is often referred to as boulder clay.
TOPOGRAPHY	The arrangement of the physical features of an area.
